

Installation Guide

1. For Android support you need to install all NVPACK's SDK, and install OSIG file into project.
2. For activation VR mode, please check the Player Settings and click on Virtual Reality Supported checkbox.
3. You can do nothing for testing your game on PC, just build and play for PC.

Post Effects installation for best graphics

All post process effect scripts need to be attached to main camera object.

Point Light must contain Sun Shafts script with attached camera and this camera should be rendering depth only. It's using for game over effect.

Controls

The controls for gameplay are easy. You can just hold mouse button and bullet object will be spawned. It described in the script Shooting.cs

The "Player" game object in Hierarchy window as Parent object need to be a holder for spawning in the world coordinates anywhere.

"Main Camera" as child of "Player" object because in VR mode camera rotations use from HMD. For rotating camera for PC builds without VR mode the "Main Camera" must be contain CameraRotation script.

"Main Camera" must contain also main gameplay logic script called "InZoneSpawn" and AudioSource.

Shooting script need to be attached on Main Camera because when player shooting need to generate the new bullet prefab

Bullet object must contain Box Collider or any geometric form of collider and Rigidbody component also need attach Destroying script for destroying bullets if they not collides with objects

Scripts

-InZoneSpawn	//Main script for gameplay logic placed on main camera
-AnimationFlower	//Script only for Flower prefab
-AnimationSpeed	//This script control tentacles of big jellyfish like a world
reaction by sound	
-CameraFacingBillboard	//Using for facing object to player
-CameraRotation	//Turn off from main camera for VR mode
-Destroying	//Destroying objects with time
-DestroyingTimer	//Any advanced destroying object
-Explosions	//This script using on shark object and sphere like a Flower
prefab	
-LookAt	//Simple Look At Object
-RandomColors	//Script using for Sphere prefab
-RotateObject	//Rotating any objects
-Shooting	//Shooting player script

```
-SoundInTact          //Control sound in tact, script using for particle and toon
shader
-SphereLogic          //Script only for sphere prefab, using for random scaling of
object and change the colors
-UVW_Animated          //Script animation of UVW map for Medusa and background
abstractions
```

Modifying gameplay and expanding Prefabs

1. For fast build up prefabs at first you will need bake animation for object in other 3D Graphics packages for example 3DS Max, Maya etc.

2. For adding new game object you will need to make new prefab with pre-baked animation from your model imported from any 3D Graphics packages or create with standard animation tool in the game engine.

3. Set the any state of pre-baked animation example Store in root for Legacy animations, or generic for Animator component

4. Create a proper structure in the hierarchy window for the future of prefab like:
"Parent" as general Holder will be spawn in world coordinates -> Child_1 (Your model with pre-baked animations) -> Child_2 (Score object as Text Mesh)

4.1. The parent object can be empty GameObject and nothing be contains. Its just a Holder

4.2. Child_1 must contain: Box Collider or any geometry form of collider marked as Trigger, Explosions.cs component for explosion effects or sounds.
It can also be including animations and AudioSource for play kick and explosion sounds.

4.3. Child_2 must be TextMesh, the Text Mesh can using animation for funny visual effects.

5. Next you will need to make prefab after this steps

6. Add a new object element in "Objects" list of "InZoneSpawn" script and put your made prefab in that Object list placed on Main Camera gameObject

6.1. "InZoneSpawn" script must necessarily contain Abstractions for background effects

6.2. You can easy modifying this script as you want. It contains comments.

7. See example like a Sphere prefab.

8. See other scripts for more information about how it can be modified

You can add some new effects but need place them in to Child_1, you can change any post-effects for changing graphics.

All post-effects scripts placing on Main Camera.

Conclusion

You do not need any setup project, just follow the instructions and actions described in the scripts.
